# re:mobidyc

the overview

# Multi-Agent Simulation

stage species

agent definition

Nauplius is EAffinis with  
age [day].

Copepodite is EAffinis with  
age [day]  
heading [degree].

action definition

to random\_walk is

my d/dt x' = v \* cos(theta)

my d/dt y' = v \* sin(theta)

where

theta = uniform 0 [degree] to 360 [degree]

v = normal 0 [m/s] sigma the speed.

to swim is

when uniform 0 to 1 < 0.3

my d/dt x' = the speed \* cos(my heading)

my d/dt y' = the speed \* sin(my heading)

the d/dt heading' = (normal 0 sigma 2) [degree/s].

task definition

Nauplius random\_walk

where

the speed -> 0.3[mm/s].

Copepodite swim

where

the heading -> my heading

the speed -> 1[mm/s].

Nauplius

Copepodite

# Expected applications

Ecology

Biology

Ecotoxicology

climate change

living marine resource management

aquaculture

# History

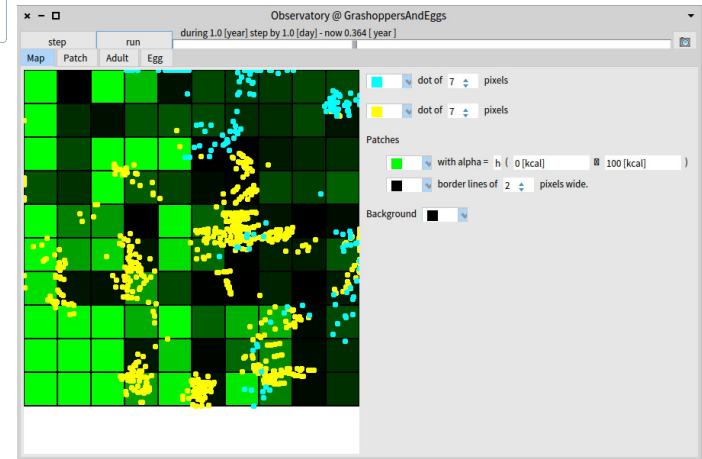

## MoBIDyC

- on 32bit VisualWorks
- development started in 1996, gained its full form in 2002, and still in use

## re:mobidyC

- on 64bit Pharo 10 + petitparser2
- open source at <https://github.com/ReMobidyC/ReMobidyC/>
- from the same design principles, we re-designed and added new technical elements.

# Features inherited from the original MoBIDyC

- discrete-time individual-based simulation
  - Turtles + Cellular Automata
- modeling without programming skills
  - modeling with minimal coding
- 25 primitives from MoBIDyC.
  - move, eat, kill, die, stage, spawn, ...

In re:mobidyc, we added a few design principles

- reliable models
  - referential transparency: synchronous updates of variables
  - type checking: check models without testing
  - termination: no infinite loop
- reviewable results
  - traceability : record all attributes of all agents at all time steps
  - reproducibility : always the same result from the same model and the same initial conditions

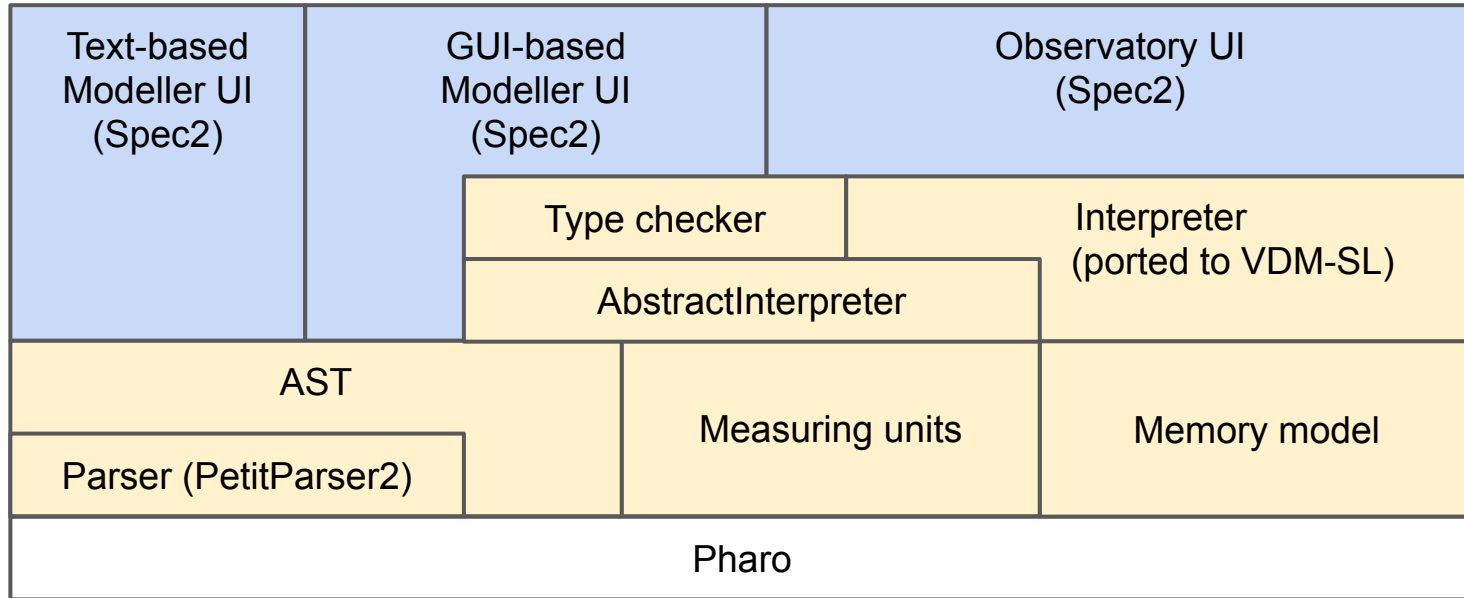

# constructing DSL on Pharo

# overview of re:mobidyc

- Original modeling language
  - domain specific modeling language
  - syntax definition
  - formal semantics ... implement in Pharo first, and then specify in formal language (VDM-SL)
  - memory model
- Pharo
  - cross platform
  - high productivity
  - Spec2 and PetitParser2

# Implementation Layers

# Spec2 + PetitParser2 → easy construction of GUI for DSL

The screenshot shows a GUI with two main panels: "Task definition" and "Task Specialization".

**Task definition:**

- Actions:** A list containing "verb", "random\_walk", and "swim". "swim" is selected.
- Template:** A text area containing:

```
to swim is
when uniform 0 to 1 < 0.3
my d/dt x' = the speed*cos(my heading)
my d/dt y' = the speed*sin(my heading)
my d/dt heading' = normal 0 mean 2 [degree/s].
```

**Task Specialization:**

- swim:** A dropdown menu with "nearest" selected.
- placeholder:** A text field containing "the speed".
- specialized:** A text field containing "1 [mm/s]".

```
(self newSourceWith: RMDGrammar new actionDefinition)
...
highlights: Array new;
whenLastValidSyntaxNodeChangedDo: [ :syntaxNode | ];
yourself.
```

```
SpTextPresenter << #RMDSourceTextPresenter
traits: {TRMDPresenter};
slots: {
  #syntaxNode => ObservableSlot .
  #lastValidSyntaxNode => ObservableSlot .
  #highlights => ObservableSlot .
  #highlightColor => ObservableSlot .
  #parser };
tag: 'Widgets';
package: 'ReMobidyc-Spec2'
```

## actionDefinition

```
^ self actionDefinitionHeaderLine , self whenClause optional
, self withClause optional
, self actionDefinitionAttributePart optional
, self actionDefinitionUtilityPart optional
, '.' asPPParser trimBlanks , #newline asPPParser trimBlanks optional
==> [ :array | ... ]
```

# need for original memory model: the time-course matters

The objective of re:mobidyc is to enable users to analyze

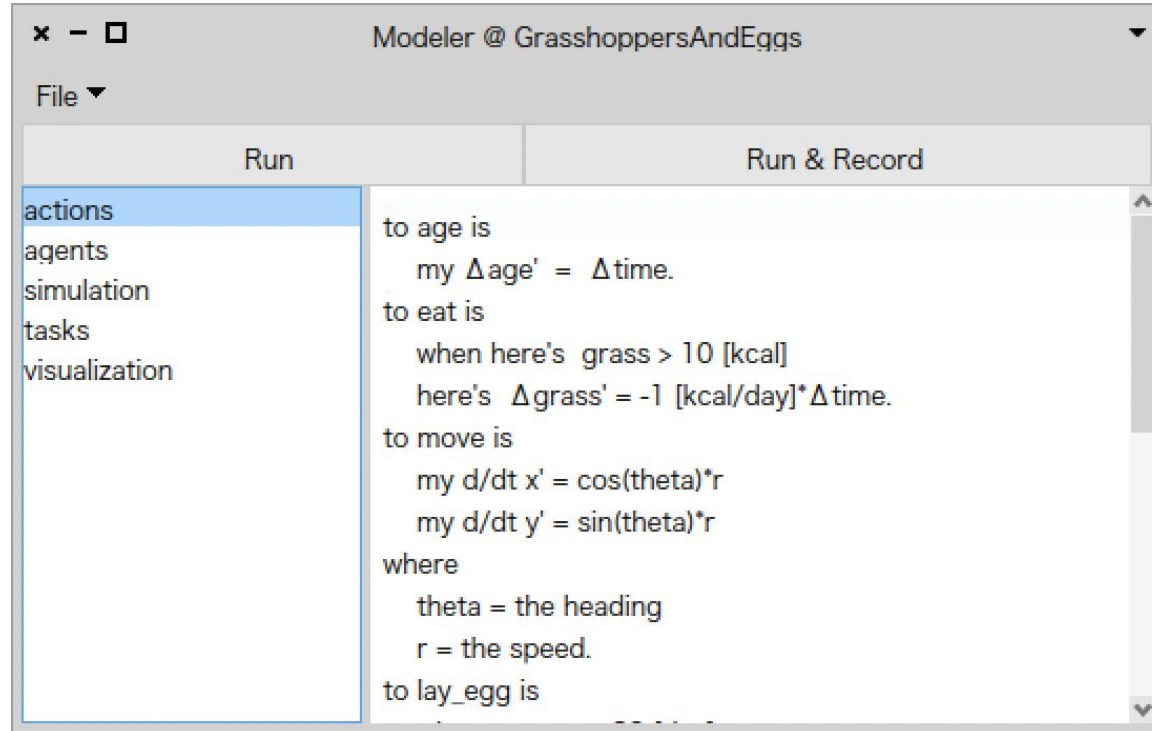

- what happens
- why it happens
- how it happens

We need a memory model with

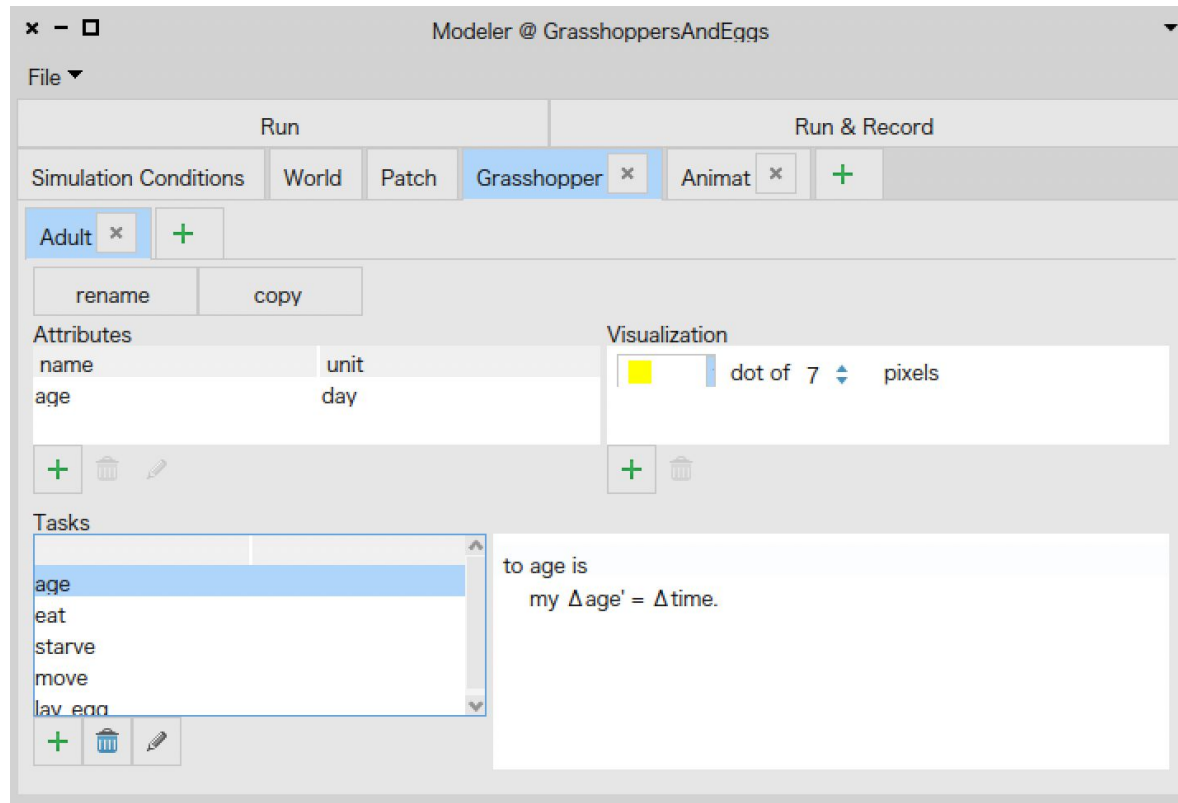

- lightweight snapshot
  - to trace cause and effect
- synchronous update
  - to isolate effects of each action
  - to eliminate intermediate state

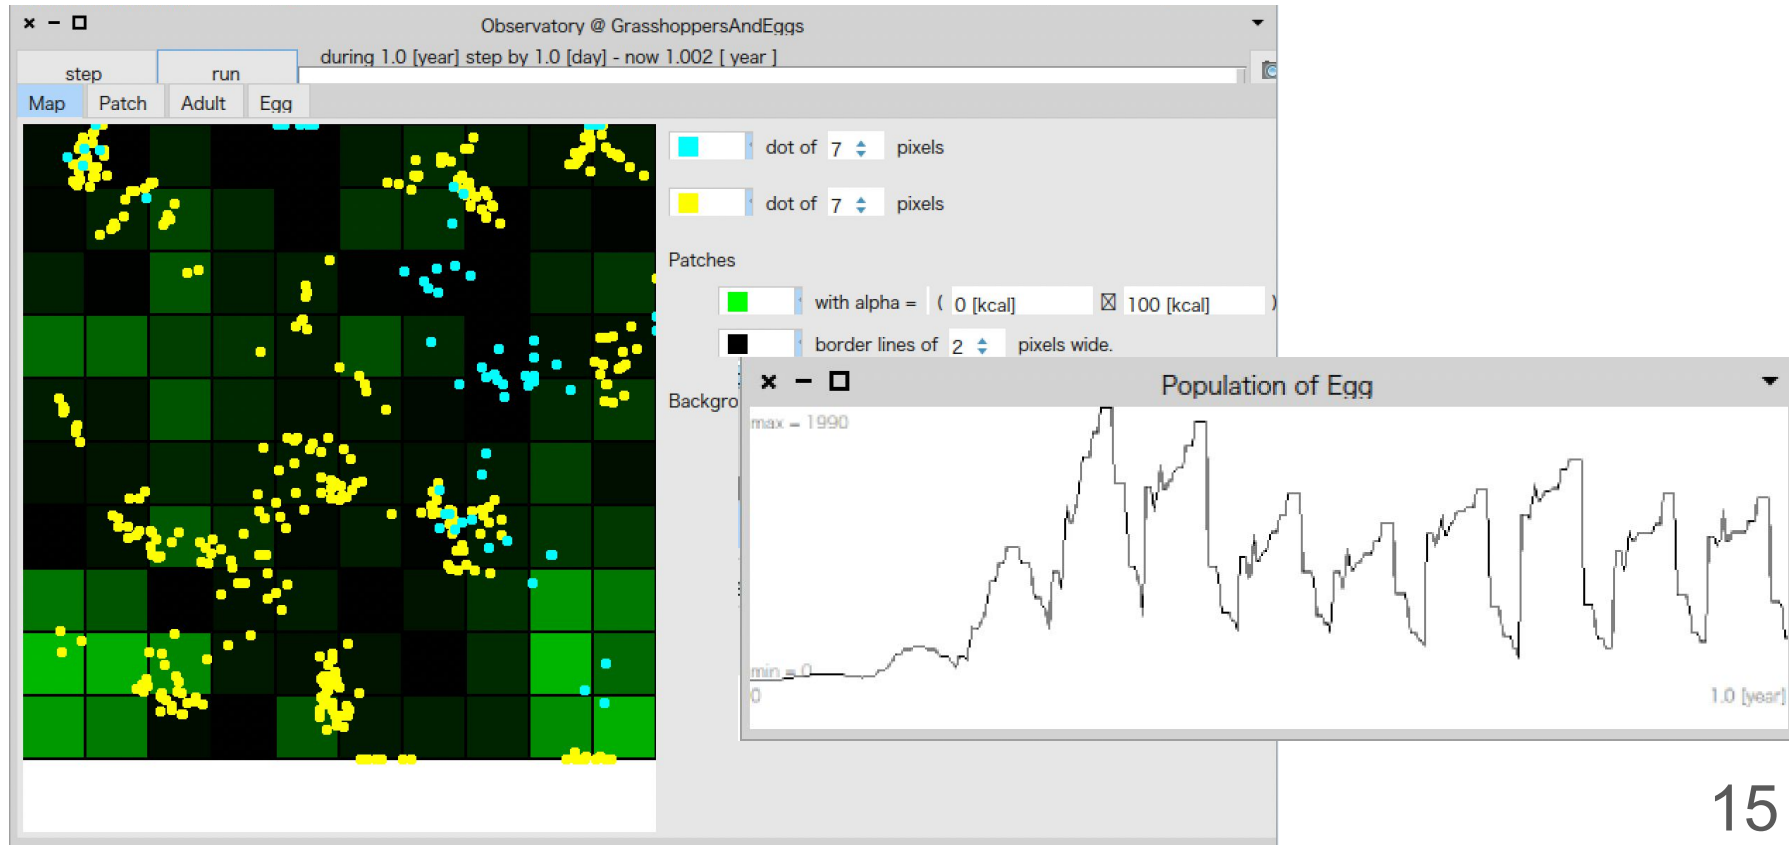

# UI : Text-based Modeler

# UI : GUI-based Modeler

# UI : Observatory

# modeling with agents

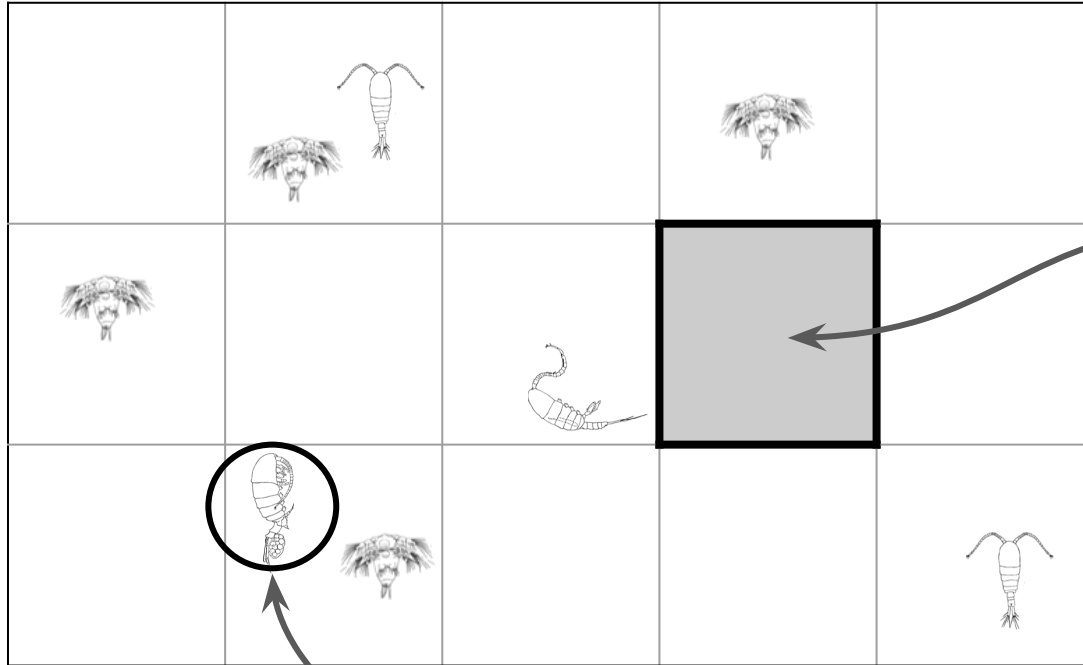

# three kinds of agents

**World:** global environment

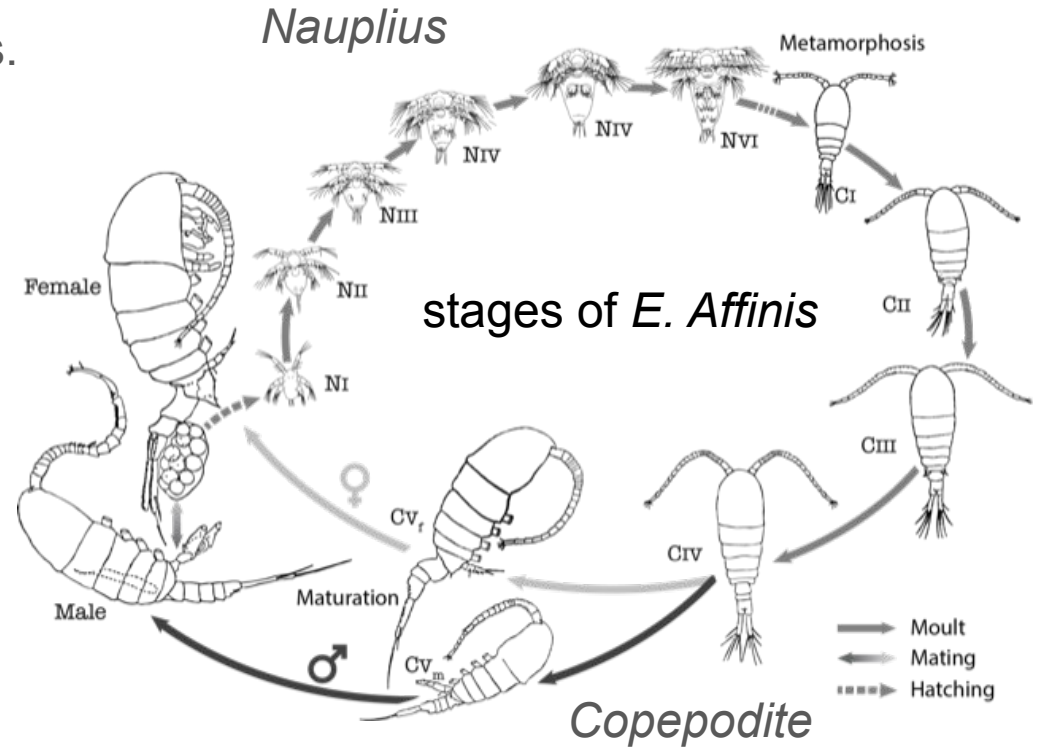

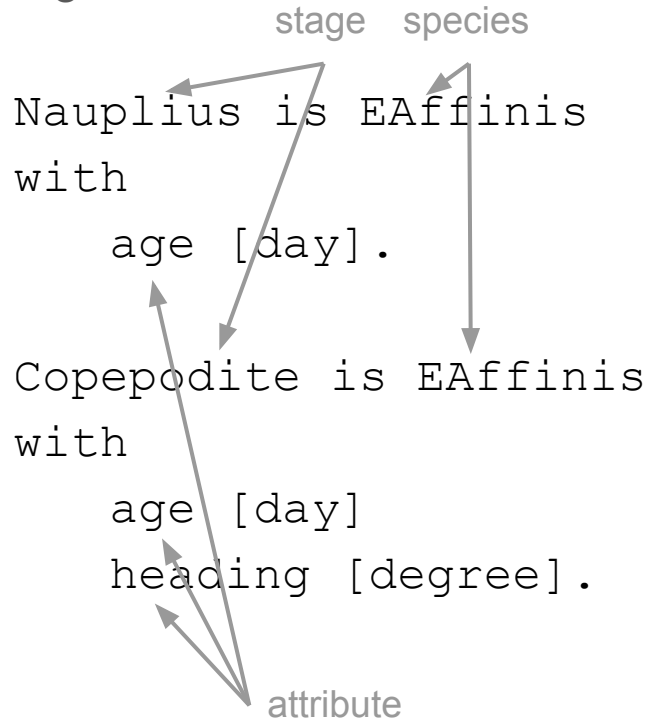

**Patch:** local environment

**Animat:** individual body

# Agents

- An agent has a set of attributes.
- e.g.

# Interactions

## Actions (verb)

- A verb updates attributes of interacting agents.
- A verb is either *vi* or *vt*.
- e.g.            verb                            updates on attributes

to random\_walk is

```
my d/dt x' = v * cos(theta)
my d/dt y' = v * sin(theta)
```

where

```
theta = uniform 0 [degree] to
360 [degree]
v = normal 0 sigma the speed.
```

local definitions

## Tasks (sentence)

- A task defines interaction among agents.
- A task is either S+V or S+V+O
- The interpreter performs a task for every instance of the subject agent at every time step.
- e.g.

```
Nauplius random_walk
where
    the speed -> 0.3[mm/s].
```

```
delta_x += v * cos(theta) * timestep;
```

# Interactions

## Actions (verb)

- A verb updates attributes of interacting agents.
- A verb is either *vi* or *vt*.
- e.g.

to random\_walk is

```
my d/dt x' = v * cos(theta)
```

```
my d/dt y' = v * sin(theta)
```

where

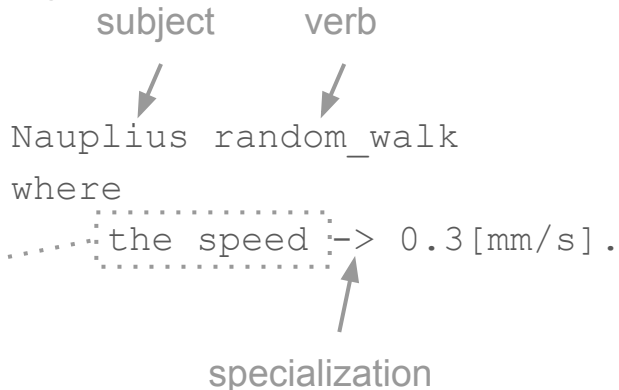

```
theta = uniform 0 [degree] to
```

```
360 [degree]
```

```
v = normal 0 sigma the speed.
```

## Tasks (sentence)

- A task defines interaction among agents.
- A task is either S+V or S+V+O
- The interpreter performs a task for every instance of the subject agent at every time step.
- e.g.

# major features of the re:mobidyc modeling language

- no messaging
- no inheritance
- no `become` : primitive
- no while-loop
- no recursion
- non-turing complete
- no string, no bool, float is the only first-class object

but has

- static typing
- type casting
- templates
- time-series memory with synchronous update
- termination because no loop!
- instance creation trace

to model interactions among the global environment, local environment patches, and animats. 21

# Types

in a language where the only FCO is float

# static typing with measuring units

## Animat definitions

```
Nauplius is EAffinis with
  x [m]
  y [m]
  heading [degree].
```

The system converts values into SI coherent units so that all computation will be in coherent SI. Also [rad],[°C],[°F] are handled as SI base units.

## Type checking on attribute definitions

expression    my  $\Delta x'$  = v \* cos(theta) \*  $\Delta$ time

unit            [m]        =        [mm/s] \* [1] \* [s] = [mm]

SI coherent unit [m]             $\longleftrightarrow$  [m]

the both types agree

# detecting type error

## Animat definitions

```
Nauplius is EAffinis with
  x [m]
  y [m]
  heading [degree].
```

## Type checking on attribute definitions

expression	$my \Delta x' = v * \cos(\theta) * \Delta time$
	
unit	$[m] = [mm/s] * [1] = [mm/s]$
	
SI coherent unit	$[m] \longleftrightarrow [m/s]$

type error !

# type casting with measuring units

- **de-unit casting**

(cm) x  
where x = 1.0 [mm]  
= 0.1

1.0 [mm] = 0.001 [m]

0.001 [m] = 0.1 [cm]

- **en-unit casting**

x [cm]  
where x = 3.0  
= 0.03 [m]

3.0 has no dimension.

3.0 [cm] = 0.03 [m]

# time-series memory with synchronous updates

re:mobidyc = computing big sequences of numbers

# The time-course matters

The objective of re:mobidyc is to enable users to analyze

- what happens
- why it happens
- how it happens

We need a memory model with

- lightweight snapshot
  - to trace cause and effect
- synchronous update
  - to isolate effects of each action
  - to eliminate intermediate state

# three cells per address

# Summary

moving forward

# Summary

- multi-agent simulator
  - re:realization of Object Orientation as a modeling language
    - de-centralized autonomous entities interacting each other.
  - open source at <https://github.com/ReMobidyc/ReMobidyc/>
  - built on Pharo 10
  - for scientific research of biology, ecology and ecotoxicology
- Future work
  - complete 25 primitives from MoBIDyC
  - formal specification
  - memory models with DBMS backends (RDB, GemStone/S, and so on)
  - debugger
  - git interface
  - computation server
  - data analysis environment
  - visualization
  - verification

Thank you!
